WO 01/70232 A1

PROTEASE INHIBITORS

FIELD OF THE INVENTION

This invention relates in general to C₁-6alkyl-4-amino-azepan-3-one protease
5 inhibitors, particularly such inhibitors of cysteine and serine proteases, more particularly
compounds which inhibit cysteine proteases, even more particularly compounds which inhibit
cysteine proteases of the papain superfamily, yet more particularly compounds which inhibit
cysteine proteases of the cathepsin family, most particularly compounds which inhibit
cathepsin K. Such compounds are particularly useful for treating diseases in which cysteine
10 proteases are implicated, especially diseases of excessive bone or cartilage loss, e.g.,
osteoporosis, periodontitis, and arthritis; and certain parasitic diseases, e.g., malaria.

BACKGROUND OF THE INVENTION

Cathepsins are a family of enzymes which are part of the papain superfamily of
15 cysteine proteases. Cathepsins B, H, L, N and S have been described in the literature.
Recently, cathepsin K polypeptide and the cDNA encoding such polypeptide were disclosed in
U.S. Patent No. 5,501,969 (called cathepsin O therein). Cathepsin K has been recently
expressed, purified, and characterized. Bossard, M. J., et al., (1996) *J. Biol. Chem.* **271**,
12517-12524; Drake, F.H., et al., (1996) *J. Biol. Chem.* **271**, 12511-12516; Bromme, D., et al.,
20 (1996) *J. Biol. Chem.* **271**, 2126-2132.

Cathepsin K has also been variously denoted as cathepsin O or cathepsin O2 in the
literature. The designation cathepsin K is considered to be the most appropriate one.

Cathepsins function in the normal physiological process of protein degradation in
animals, including humans, e.g., in the degradation of connective tissue. However, elevated
25 levels of these enzymes in the body can result in pathological conditions leading to disease.
Thus, cathepsins have been implicated as causative agents in various disease states, including
but not limited to, infections by pneumocystis carinii, trypanoma cruzi, trypanoma brucei
brucei, and Crithidia fusciculata; as well as in schistosomiasis, malaria, tumor metastasis,
metachromatic leukodystrophy, muscular dystrophy, amyotrophy, and the like. See International
30 Publication Number WO 94/04172, published on March 3, 1994, and references cited therein.
See also European Patent Application EP 0 603 873 A1, and references cited therein. Two
bacterial cysteine proteases from *P. gingivallis*, called gingipains, have been implicated in the
pathogenesis of gingivitis. Potempa, J., et al. (1994) *Perspectives in Drug Discovery and
Design*, **2**, 445-458.

Cathepsin K is believed to play a causative role in diseases of excessive bone or cartilage loss. Bone is composed of a protein matrix in which spindle- or plate-shaped crystals of hydroxyapatite are incorporated. Type I collagen represents the major structural protein of bone comprising approximately 90% of the protein matrix. The remaining 10% of matrix is
5 composed of a number of non-collagenous proteins, including osteocalcin, proteoglycans, osteopontin, osteonectin, thrombospondin, fibronectin, and bone sialoprotein. Skeletal bone undergoes remodelling at discrete foci throughout life. These foci, or remodelling units, undergo a cycle consisting of a bone resorption phase followed by a phase of bone replacement.

10 Bone resorption is carried out by osteoclasts, which are multinuclear cells of hematopoietic lineage. The osteoclasts adhere to the bone surface and form a tight sealing zone, followed by extensive membrane ruffling on their apical (i.e., resorbing) surface. This creates an enclosed extracellular compartment on the bone surface that is acidified by proton pumps in the ruffled membrane, and into which the osteoclast secretes proteolytic enzymes.
15 The low pH of the compartment dissolves hydroxyapatite crystals at the bone surface, while the proteolytic enzymes digest the protein matrix. In this way, a resorption lacuna, or pit, is formed. At the end of this phase of the cycle, osteoblasts lay down a new protein matrix that is subsequently mineralized. In several disease states, such as osteoporosis and Paget's disease, the normal balance between bone resorption and formation is disrupted, and there is a net loss
20 of bone at each cycle. Ultimately, this leads to weakening of the bone and may result in increased fracture risk with minimal trauma.

Several published studies have demonstrated that inhibitors of cysteine proteases are effective at inhibiting osteoclast-mediated bone resorption, and indicate an essential role for a cysteine proteases in bone resorption. For example, Delaisse, *et al.*, *Biochem. J.*, **1980**, *192*,
25 *365*, disclose a series of protease inhibitors in a mouse bone organ culture system and suggest that inhibitors of cysteine proteases (e.g., leupeptin, Z-Phe-Ala-CHN₂) prevent bone resorption, while serine protease inhibitors were ineffective. Delaisse, *et al.*, *Biochem. Biophys. Res. Commun.*, **1984**, *125*, *441*, disclose that E-64 and leupeptin are also effective at preventing bone resorption *in vivo*, as measured by acute changes in serum calcium in rats on
30 calcium deficient diets. Lerner, *et al.*, *J. Bone Min. Res.*, **1992**, *7*, *433*, disclose that cystatin, an endogenous cysteine protease inhibitor, inhibits PTH stimulated bone resorption in mouse calvariae. Other studies, such as by Delaisse, *et al.*, *Bone*, **1987**, *8*, *305*, Hill, *et al.*, *J. Cell. Biochem.*, **1994**, *56*, *118*, and Everts, *et al.*, *J. Cell. Physiol.*, **1992**, *150*, *221*, also report a correlation between inhibition of cysteine protease activity and bone resorption. Tezuka, *et al.*,

J. Biol. Chem., 1994, 269, 1106, Inaoka, *et al.*, *Biochem. Biophys. Res. Commun.*, 1995, 206, 89 and Shi, *et al.*, *FEBS Lett.*, 1995, 357, 129 disclose that under normal conditions cathepsin K, a cysteine protease, is abundantly expressed in osteoclasts and may be the major cysteine protease present in these cells.

5 The abundant selective expression of cathepsin K in osteoclasts strongly suggests that this enzyme is essential for bone resorption. Thus, selective inhibition of cathepsin K may provide an effective treatment for diseases of excessive bone loss, including, but not limited to, osteoporosis, gingival diseases such as gingivitis and periodontitis, Paget's disease, hypercalcemia of malignancy, and metabolic bone disease. Cathepsin K levels have also been
10 demonstrated to be elevated in chondroclasts of osteoarthritic synovium. Thus, selective inhibition of cathepsin K may also be useful for treating diseases of excessive cartilage or matrix degradation, including, but not limited to, osteoarthritis and rheumatoid arthritis. Metastatic neoplastic cells also typically express high levels of proteolytic enzymes that degrade the surrounding matrix. Thus, selective inhibition of cathepsin K may also be useful
15 for treating certain neoplastic diseases.

 Several cysteine protease inhibitors are known. Palmer, (1995) *J. Med. Chem.*, 38, 3193, disclose certain vinyl sulfones which irreversibly inhibit cysteine proteases, such as the cathepsins B, L, S, O2 and cruzain. Other classes of compounds, such as aldehydes, nitriles, α -ketocarbonyl compounds, halomethyl ketones, diazomethyl ketones, (acyloxy)methyl
20 ketones, ketomethylsulfonium salts and epoxy succinyl compounds have also been reported to inhibit cysteine proteases. See Palmer, *id.*, and references cited therein.

 U.S. Patent No. 4,518,528 discloses peptidyl fluoromethyl ketones as irreversible inhibitors of cysteine protease. Published International Patent Application No. WO 94/04172, and European Patent Application Nos. EP 0 525 420 A1, EP 0 603 873 A1, and EP 0 611 756
25 A2 describe alkoxymethyl and mercaptomethyl ketones which inhibit the cysteine proteases cathepsins B, H and L. International Patent Application No. PCT/US94/08868 and and European Patent Application No. EP 0 623 592 A1 describe alkoxymethyl and mercaptomethyl ketones which inhibit the cysteine protease IL-1 β convertase. Alkoxymethyl and mercaptomethyl ketones have also been described as inhibitors of the serine protease
30 kininogenase (International Patent Application No. PCT/GB91/01479).

 Azapeptides which are designed to deliver the azaamino acid to the active site of serine proteases, and which possess a good leaving group, are disclosed by Elmore *et al.*, *Biochem. J.*, 1968, 107, 103, Garker *et al.*, *Biochem. J.*, 1974, 139, 555, Gray *et al.*, *Tetrahedron*, 1977, 33, 837, Gupton *et al.*, *J. Biol. Chem.*, 1984, 259, 4279, Powers *et al.*, *J. Biol. Chem.*, 1984, 259,

4288, and are known to inhibit serine proteases. In addition, *J. Med. Chem.*, **1992**, *35*, 4279, discloses certain azapeptide esters as cysteine protease inhibitors.

Antipain and leupeptin are described as reversible inhibitors of cysteine protease in McConnell et al., *J. Med. Chem.*, *33*, 86; and also have been disclosed as inhibitors of serine protease in Umezawa et al., *45 Meth. Enzymol.* 678. E64 and its synthetic analogs are also well-known cysteine protease inhibitors (Barrett, *Biochem. J.*, *201*, 189, and Grinde, *Biochem. Biophys. Acta*, *701*, 328).

1,3-diamido-propanones have been described as analgesic agents in U.S. Patent Nos. 4,749,792 and 4,638,010.

Thus, a structurally diverse variety of protease inhibitors have been identified. However, these known inhibitors are not considered suitable for use as therapeutic agents in animals, especially humans, because they suffer from various shortcomings. These shortcomings include lack of selectivity, cytotoxicity, poor solubility, and overly rapid plasma clearance. A need therefore exists for methods of treating diseases caused by pathological levels of proteases, particularly cysteine proteases, more particularly cathepsins, most particularly cathepsin K, and for novel inhibitor compounds useful in such methods.

We have now discovered a novel class of C₁₋₆alkyl-4-amino-azepan-3-one compounds which are protease inhibitors, most particularly of cathepsin K.

20

Definitions

The present invention includes all hydrates, solvates, complexes and prodrugs of the compounds of this invention. Prodrugs are any covalently bonded compounds which release the active parent drug according to Formula I *in vivo*. If a chiral center or another form of an isomeric center is present in a compound of the present invention, all forms of such isomer or isomers, including enantiomers and diastereomers, are intended to be covered herein. Inventive compounds containing a chiral center may be used as a racemic mixture, an enantiomerically enriched mixture, or the racemic mixture may be separated using well-known techniques and an individual enantiomer may be used alone. In cases in which compounds have unsaturated carbon-carbon double bonds, both the cis (Z) and trans (E) isomers are within the scope of this invention. In cases wherein compounds may exist in tautomeric forms, such as keto-enol tautomers, each tautomeric form is contemplated as being included within this invention whether existing in equilibrium or predominantly in one form.

The meaning of any substituent at any one occurrence in Formula I or any subformula thereof is independent of its meaning, or any other substituent's meaning, at any other occurrence, unless specified otherwise.

Abbreviations and symbols commonly used in the peptide and chemical arts are used herein to describe the compounds of the present invention. In general, the amino acid abbreviations follow the IUPAC-IUB Joint Commission on Biochemical Nomenclature as described in *Eur. J. Biochem.*, 158, 9 (1984).

"Proteases" are enzymes that catalyze the cleavage of amide bonds of peptides and proteins by nucleophilic substitution at the amide bond, ultimately resulting in hydrolysis. Such proteases include: cysteine proteases, serine proteases, aspartic proteases, and

Methods of Preparation

Compounds of the general formula I may be prepared in a fashion analogous to that outlined in Schemes 1 to 8.

Scheme 1

- 2-Methyl-pent-4-enoic acid ethyl ester is converted to a N-2-pyridinesulfonyl-
- 5 azapine by reduction to the aldehyde, reductive amination with allylamine, sulfonylation with 2-pyridyl sulfonyl chloride, and olefin metathesis with Grubbs' catalyst. Epoxidation with mCPBA affords a mixture of epoxides that are separable by column chromatography. The syn epoxide is converted into an amino alcohol by opening with sodium azide followed by reduction with triphenylphosphine. Acylation of the free amine with Boc-leucine and a
- 10 coupling reagent such as HBTU or EDC, followed by deprotection of the Boc group with HCl, and acylation with a variety of aromatic carboxylic acids and coupling reagents such as HBTU or EDC gives the intermediate alcohols. Final oxidation with Dess-Martin periodinane and HPLC affords the desired ketones.

Scheme 2

- 5-Hexen-2-one is converted to a N-carbobenzyloxy-azapine by reductive amination with allylamine, protection with carbobenzyloxyl chloride, and olefin metathesis with Grubbs' catalyst. Epoxidation with mCPBA affords a mixture of epoxides that are separable by column chromatography. Each epoxide is converted into an amino alcohol by opening with sodium azide followed by reduction with triphenylphosphine. Acylation of the free amine with Boc-leucine and a coupling reagent such as HBTU or EDC, followed by deprotection of the Cbz group by hydrogenolysis provides the secondary amines which are in turn sulfonylated with 2-pyridine sulfonylchloride. Deprotection of the Boc groups with HCl and acylation with a variety of aromatic carboxylic acids and coupling reagents such as HBTU or EDC gives the intermediate alcohols. Final oxidation with Dess-Martin periodinane and HPLC affords the desired ketones.

Scheme 3

Carbobenzyloxy-D-alaninol (Cbz-D-alaninol) is first converted to an iodide, then is

5 reacted with allyl Grignard with a copper (I) catalyst or a similar allyl organometallic reagent. The amine is then alkylated with allyl iodide. Grubbs' catalyst is then used to form the azapine ring by ring closing metathesis. Epoxidation of the alkene followed by separation of the diastereomers followed by opening of the epoxide of the minor component with sodium azide provides the intermediate azido alcohol. Reduction of the azide

10 followed by acylation of the amine with a protected amino acid such as Boc-leucine, followed by deprotection of the Cbz gives the intermediate secondary amine, which is then sulfonylated with a sulfonyl chloride such as pyridine sulfonyl chloride. Deprotection of the Boc group followed by acylation with an acylating agent such as quinoline-6-carboxylic

acid, HBTU, NMM, and final oxidation of the secondary alcohol to the ketone with an oxidant such as sulfur trioxide-pyridine or Dess-Martin periodinane provides the desired products.

Scheme 4

Deuterated inhibitors can be prepared from the parent inhibitors such as benzofuran-2-carboxylic acid {(S)-3-methyl-1-[(4S,7R)-7-methyl-3-oxo-1-(pyridine-2-sulfonyl)-azepan-4-ylcarbamoyl]-butyl}-amide by treating with a base such as triethyl
 10 amine and stirring for several days in a deuterated protic solvent such as CD₃OD: D₂O.

Scheme 5

15 Intermediate (S)-3-Cyclohexyl-N-((3S,4S,7R)-3-hydroxy-7-methyl-azepan-4-yl)-2-methyl-propionamide, as described in Scheme 3 (using Boc-cyclohexylalanine instead of Boc-L-leucine), is reductively aminated with an aldehyde or a ketone such as propionaldehyde, then treated with a reducing agent such as sodium borohydride. Deprotection of the Boc group followed by acylation with an acylating agent such as 2-furan carboxylic acid,

HBTU, NMM, and final oxidation of the secondary alcohol to the ketone with an oxidant such as sulfur trioxide-pyridine provides the desired products.

Scheme 6

5

Intermediate [(S)-1-((S)-3-Hydroxy-azepan-4-ylcarbonyl)-3-methyl-butyl]-carbamic acid tert-butyl ester, as described in Scheme 3, is acylated with an isocyanate such as (S)-(-)-2-isocyanato-4-methylvaleric acid methyl ester. Deprotection of the Boc group followed by acylation with an acylating agent such as benzofuran-2-carboxylic acid, HBTU, NMM, and final oxidation of the secondary alcohol to the ketone with an oxidant such as Dess-Martin periodinane or sulfur trioxide-pyridine provides the desired products.

The synthesis of the C-5 methyl azepinone, 4,5 (R,S)-benzofuran-2-carboxylic acid {(S)-3-methyl-1-[5-methyl-3-oxo-1-(pyridine-2-sulfonyl)-azepan-4-ylcarbamoyl]-butyl}amide, (Example 61) is outlined above in Scheme 7. Michael addition of nitromethane to ethyl crotonate 7-1 followed by reduction of the

5 intermediate ester with a reducing agent such as diisobutyl aluminum hydride (Dibal-H) provides the aldehyde 7-2. Reductive amination of 7-2 with N-benzyl ethanolamine in the presence of a reducing agent such as sodium triacetoxyborohydride provides the nitro-alcohol 7-3. Oxidation of 7-3 using an

10 oxidant common to the art such as DMSO and oxalyl chloride followed by treatment of the crude intermediate aldehyde with a base such as triethylamine effects the nitro-aldol reaction to give the azepanol 7-4. Reduction of the nitro group with zinc in the presence of hydrochloric acid followed by coupling of the resulting amine with N-Boc-leucine in the presence of a coupling agent common to the art such as EDC provides intermediate 7-5. Reductive removal of the N-benzyl moiety with

15 hydrogen gas in the presence of a catalyst such as 10% Pd on carbon followed by sulfonylation with a sulfonyl chloride in the presence of a base such as N-methylmorpholine or triethyl amine provides the sulfonamide intermediate 7-6. Removal of the N-Boc protecting group under acidic conditions followed by coupling of the resulting amine salt with benzofuran-2-carboxylic acid and oxidation

20 of the alcohol with an oxidant common to the art such as pyridine sulfur trioxide complex or Dess-Martin periodinane provides the ketone 7. The individual diastereomers of 7-7 may be separated by HPLC methods to provide diastereomers 7-8, 7-9, 7-10 and 7-11.

Scheme 8

- Intermediate (2R,5R,6R)-5-Amino-6-hydroxy-2-methyl-azepane-1-carboxylic acid benzyl ester (derived from the major epoxide of Scheme 3) is protected with Boc anhydride.
- 5 Then, the Cbz group is removed by hydrogenolysis. Sulfonylation is then accomplished with 2-pyridine sulfonyl chloride, and the Boc group is removed with hydrochloric acid in dioxane. The primary amine is then coupled with 2-biphenyl-3-yl-4-methyl-pentanoic acid (as described in. *J. Am. Chem. Soc.* **1997**, *120*, 9114), then the secondary alcohol to the ketone with an oxidant such as Dess-Martin periodinane or sulfur trioxide-pyridine. The
- 10 azepanone is then epimerized using triethylamine in MeOH to provide a mixture of diastereomers. The desired compound is obtained by separation of the diastereomers using chiral HPLC.

The starting materials used herein are commercially available amino acids or are prepared by routine methods well known to those of ordinary skill in the art and can be

15 found in standard reference books, such as the COMPENDIUM OF ORGANIC SYNTHETIC METHODS, Vol. I-VI (published by Wiley-Interscience).

Coupling methods to form amide bonds herein are generally well known to the art. The methods of peptide synthesis generally set forth by Bodansky *et al.*, THE PRACTICE OF PEPTIDE SYNTHESIS, Springer-Verlag, Berlin, 1984; E. Gross and J. Meienhofer,

20 THE PEPTIDES, Vol. 1, 1-284 (1979); and J.M. Stewart and J.D. Young, SOLID PHASE

PEPTIDE SYNTHESIS, 2d Ed., Pierce Chemical Co., Rockford, Ill., 1984. are generally illustrative of the technique and are incorporated herein by reference.

Synthetic methods to prepare the compounds of this invention frequently employ protective groups to mask a reactive functionality or minimize unwanted side reactions.

5 Such protective groups are described generally in Green, T.W, PROTECTIVE GROUPS IN ORGANIC SYNTHESIS, John Wiley & Sons, New York (1981). The term "amino protecting groups" generally refers to the Boc, acetyl, benzoyl, Fmoc and Cbz groups and derivatives thereof as known to the art. Methods for protection and deprotection, and replacement of an amino protecting group with another moiety are well known.

10 Acid addition salts of the compounds of Formula I are prepared in a standard manner in a suitable solvent from the parent compound and an excess of an acid, such as hydrochloric, hydrobromic, hydrofluoric, sulfuric, phosphoric, acetic, trifluoroacetic, maleic, succinic or methanesulfonic. Certain of the compounds form inner salts or zwitterions which may be acceptable. Cationic salts are prepared by treating the parent
15 compound with an excess of an alkaline reagent, such as a hydroxide, carbonate or alkoxide, containing the appropriate cation; or with an appropriate organic amine. Cations such as Li^+ , Na^+ , K^+ , Ca^{++} , Mg^{++} and NH_4^+ are specific examples of cations present in pharmaceutically acceptable salts. Halides, sulfate, phosphate, alkanoates (such as acetate and trifluoroacetate), benzoates, and sulfonates (such as mesylate) are examples of anions
20 present in pharmaceutically acceptable salts.

This invention also provides a pharmaceutical composition which comprises a compound according to Formula I and a pharmaceutically acceptable carrier, diluent or excipient. Accordingly, the compounds of Formula I may be used in the manufacture of a medicament. Pharmaceutical compositions of the compounds of Formula I prepared as
25 hereinbefore described may be formulated as solutions or lyophilized powders for parenteral administration. Powders may be reconstituted by addition of a suitable diluent or other pharmaceutically acceptable carrier prior to use. The liquid formulation may be a buffered, isotonic, aqueous solution. Examples of suitable diluents are normal isotonic saline solution, standard 5% dextrose in water or buffered sodium or ammonium acetate
30 solution. Such formulation is especially suitable for parenteral administration, but may also be used for oral administration or contained in a metered dose inhaler or nebulizer for insufflation. It may be desirable to add excipients such as polyvinylpyrrolidone, gelatin, hydroxy cellulose, acacia, polyethylene glycol, mannitol, sodium chloride or sodium citrate.

Alternately, these compounds may be encapsulated, tableted or prepared in an emulsion or syrup for oral administration. Pharmaceutically acceptable solid or liquid carriers may be added to enhance or stabilize the composition, or to facilitate preparation of the composition. Solid carriers include starch, lactose, calcium sulfate dihydrate, terra alba, magnesium stearate or stearic acid, talc, pectin, acacia, agar or gelatin. Liquid carriers include syrup, peanut oil, olive oil, saline and water. The carrier may also include a sustained release material such as glyceryl monostearate or glyceryl distearate, alone or with a wax. The amount of solid carrier varies but, preferably, will be between about 20 mg to about 1 g per dosage unit. The pharmaceutical preparations are made following the conventional techniques of pharmacy involving milling, mixing, granulating, and compressing, when necessary, for tablet forms; or milling, mixing and filling for hard gelatin capsule forms. When a liquid carrier is used, the preparation will be in the form of a syrup, elixir, emulsion or an aqueous or non-aqueous suspension. Such a liquid formulation may be administered directly p.o. or filled into a soft gelatin capsule.

For rectal administration, the compounds of this invention may also be combined with excipients such as cocoa butter, glycerin, gelatin or polyethylene glycols and molded into a suppository.

Process for Synthesis of Inventive Compounds

Referring to Schemes 1-8 herein above, the present invention provides a process for the synthesis of compounds of Formula (I) comprising the step of oxidizing the appropriate compound of Formula (II) with an oxidant to provide the compound of Formula (I) as a mixture of diastereomers. Preferably the oxidant is sulfur trioxide-pyridine complex.

5 Referring to Scheme 4, the present invention also provides a process for the synthesis of deuterated compounds of Formula (I). Specifically, when a deuterated isomer is desired, an additional step, following the oxidation step, of deuterating the protonated isomer with a deuterating agent to provide the deuterated compound of Formula (I) as a mixture of diastereomers is added to the synthesis. Preferably, the deuterating agent is
10 $\text{CD}_3\text{OD}:\text{D}_2\text{O}$ (10:1) in triethylamine.

The process further comprises the step of separating the diastereomers of Formula (I) by separating means, preferably by high pressure liquid chromatography (HPLC).

Utility of the Present Invention

15 The compounds of Formula I are useful as protease inhibitors, particularly as inhibitors of cysteine and serine proteases, more particularly as inhibitors of cysteine proteases, even more particularly as inhibitors of cysteine proteases of the papain superfamily, yet more particularly as inhibitors of cysteine proteases of the cathepsin family, most particularly as inhibitors of cathepsin K. The present invention also provides
20 useful compositions and formulations of said compounds, including pharmaceutical compositions and formulations of said compounds.

The present compounds are useful for treating diseases in which cysteine proteases are implicated, including infections by pneumocystis carinii, trypanosoma cruzi, trypanosoma brucei, and Crithidia fusciculata; as well as in schistosomiasis, malaria, tumor metastasis,
25 metachromatic leukodystrophy, muscular dystrophy, amyotrophy; and especially diseases in which cathepsin K is implicated, most particularly diseases of excessive bone or cartilage loss, including osteoporosis, gingival disease including gingivitis and periodontitis, arthritis, more specifically, osteoarthritis and rheumatoid arthritis, Paget's disease; hypercalcemia of malignancy, and metabolic bone disease.

30 Parasites known to utilize cysteine proteases in their life cycle (and the diseases caused by these parasites) include *Trypanosoma cruzi*, *Trypanosoma Brucei* [trypanosomiasis (African sleeping sickness, Chagas disease)], *Leishmania mexicana*, *Leishmania pifanoi*, *Leishmania major* (leishmaniasis), *Schistosoma mansoni* (schistosomiasis), *Onchocerca volvulus* [onchocerciasis (river blindness)] *Brugia pahangi*,

Entamoeba histolytica, *Giardia lamblia*, the helminths, *Haemonchus contortus* and *Fasciola hepatica*, as well as helminths of the genera *Spirometra*, *Trichinella*, *Necator* and *Ascaris*, and protozoa of the genera *Cryptosporidium*, *Eimeria*, *Toxoplasma* and *Naegleria*. The compounds of the present invention are suitable for treating diseases caused by these

5 parasites which may be therapeutically modified by altering the activity of cysteine proteases. In particular, the present compounds are useful for treating malaria by inhibiting falcipain.

Metastatic neoplastic cells also typically express high levels of proteolytic enzymes that degrade the surrounding matrix, and certain tumors and metastatic neoplasias may be

10 effectively treated with the compounds of this invention.

The present invention also provides methods of treatment of diseases caused by pathological levels of proteases, particularly cysteine and serine proteases, more particularly cysteine proteases, even more particularly cysteine proteases of the papain superfamily, yet more particularly cysteine proteases of the cathepsin family, which

15 methods comprise administering to an animal, particularly a mammal, most particularly a human in need thereof a compound of the present invention. The present invention especially provides methods of treatment of diseases caused by pathological levels of cathepsin K, which methods comprise administering to an animal, particularly a mammal, most particularly a human in need thereof an inhibitor of cathepsin K, including a

20 compound of the present invention. The present invention particularly provides methods for treating diseases in which cysteine proteases are implicated, including infections by pneumocystis carinii, trypanosoma cruzi, trypanosoma brucei, and Crithidia fusiculata; as well as in schistosomiasis, malaria, tumor metastasis, metachromatic leukodystrophy, muscular dystrophy, amyotrophy, and especially diseases in which cathepsin K is implicated, most

25 particularly diseases of excessive bone or cartilage loss, including osteoporosis, gingival disease including gingivitis and periodontitis, arthritis, more specifically, osteoarthritis and rheumatoid arthritis, Paget's disease, hypercalcemia of malignancy, and metabolic bone disease.

The present method provides treatment of diseases (in parentheses) caused by

30 infection by *Trypanosoma cruzi*, *Trypanosoma Brucei* [trypanosomiasis (African sleeping sickness, Chagas disease)], *Leishmania mexicana*, *Leishmania pifanoi*, *Leishmania major* (leishmaniasis), *Schistosoma mansoni* (schistosomiasis), *Onchocerca volvulus* [onchocerciasis (river blindness)] *Brugia pahangi*, *Entamoeba histolytica*, *Giardia lamblia*, the helminths, *Haemonchus contortus* and *Fasciola hepatica*, as well as helminths of the

genera *Spirometra*, *Trichinella*, *Necator* and *Ascaris*, and protozoa of the genera *Cryptosporidium*, *Eimeria*, *Toxoplasma* and *Naegleria* by inhibiting cysteine proteases of the papain superfamily by administering to a patient in need thereof, particularly an animal, more particularly a mammal, most particularly a human being, one or more of the above-

5 listed compounds.

Most particularly, the present invention provides a method of treating malaria, caused by infection with *Plasmodium falciparum*, by the inhibition of falcipain by administering to a patient in need thereof, particularly an animal, more particularly a mammal, most particularly a human being, one or more of the above-listed compounds.

10 The present method may be practiced by administering the above-listed compounds alone or in combination, with each other, or with other therapeutically effective compounds.

This invention further provides a method for treating osteoporosis or inhibiting

15 bone loss which comprises internal administration to a patient of an effective amount of a compound of Formula I, alone or in combination with other inhibitors of bone resorption, such as bisphosphonates (i.e., allendronate), hormone replacement therapy, anti-estrogens, or calcitonin. In addition, treatment with a compound of this invention and an anabolic agent, such as bone morphogenic protein, iproflavone, may be used to prevent bone loss or

20 to increase bone mass.

For acute therapy, parenteral administration of a compound of Formula I is preferred. An intravenous infusion of the compound in 5% dextrose in water or normal saline, or a similar formulation with suitable excipients, is most effective, although an intramuscular bolus injection is also useful. Typically, the parenteral dose will be about

25 0.01 to about 100 mg/kg; preferably between 0.1 and 20 mg/kg, in a manner to maintain the concentration of drug in the plasma at a concentration effective to inhibit cathepsin K. The compounds are administered one to four times daily at a level to achieve a total daily dose of about 0.4 to about 400 mg/kg/day. The precise amount of an inventive compound which is therapeutically effective, and the route by which such compound is best administered, is

30 readily determined by one of ordinary skill in the art by comparing the blood level of the agent to the concentration required to have a therapeutic effect.

The compounds of this invention may also be administered orally to the patient, in a manner such that the concentration of drug is sufficient to inhibit bone resorption or to achieve any other therapeutic indication as disclosed herein. Typically, a pharmaceutical

composition containing the compound is administered at an oral dose of between about 0.1 to about 50 mg/kg in a manner consistent with the condition of the patient. Preferably the oral dose would be about 0.5 to about 20 mg/kg.

No unacceptable toxicological effects are expected when compounds of the present invention are administered in accordance with the present invention.

Biological Assays

The compounds of this invention may be tested in one of several biological assays to determine the concentration of compound which is required to have a given pharmacological effect.

Determination of cathepsin K proteolytic catalytic activity

All assays for cathepsin K were carried out with human recombinant enzyme. Standard assay conditions for the determination of kinetic constants used a fluorogenic peptide substrate, typically Cbz-Phe-Arg-AMC, and were determined in 100 mM Na acetate at pH 5.5 containing 20 mM cysteine and 5 mM EDTA. Stock substrate solutions were prepared at concentrations of 10 or 20 mM in DMSO with 20 μ M final substrate concentration in the assays. All assays contained 10% DMSO. Independent experiments found that this level of DMSO had no effect on enzyme activity or kinetic constants. All assays were conducted at ambient temperature. Product fluorescence (excitation at 360 nM; emission at 460 nM) was monitored with a Perceptive Biosystems Cytofluor II fluorescent plate reader. Product progress curves were generated over 20 to 30 minutes following formation of AMC product.

Inhibition studies

Potential inhibitors were evaluated using the progress curve method. Assays were carried out in the presence of variable concentrations of test compound. Reactions were initiated by addition of enzyme to buffered solutions of inhibitor and substrate. Data analysis was conducted according to one of two procedures depending on the appearance of the progress curves in the presence of inhibitors. For those compounds whose progress curves were linear, apparent inhibition constants ($K_{i,app}$) were calculated according to equation 1 (Brandt *et al.*, *Biochemistry*, 1989, 28, 140):

$$v = V_m A / [K_a(1 + 1/K_{i,app}) + A] \quad (i)$$

where v is the velocity of the reaction with maximal velocity V_m , A is the concentration of substrate with Michaelis constant of K_m , and I is the concentration of inhibitor.

- For those compounds whose progress curves showed downward curvature
 5 characteristic of time-dependent inhibition, the data from individual sets was analyzed to give k_{obs} according to equation 2:

$$[AMC] = v_{ss} t + (v_0 - v_{ss}) [1 - \exp(-k_{obs}t)] / k_{obs} \quad (2)$$

- 10 where $[AMC]$ is the concentration of product formed over time t , v_0 is the initial reaction velocity and v_{ss} is the final steady state rate. Values for k_{obs} were then analyzed as a linear function of inhibitor concentration to generate an apparent second order rate constant (k_{obs} / inhibitor concentration or $k_{obs} / [I]$) describing the time-dependent inhibition. A complete discussion of this kinetic treatment has been fully described (Morrison *et al.*, *Adv. Enzymol. Relat. Areas Mol. Biol.*, **1988**, 61, 201).

Human Osteoclast Resorption Assay

- Aliquots of osteoclastoma-derived cell suspensions were removed from liquid nitrogen storage, warmed rapidly at 37°C and washed x1 in RPMI-1640 medium by
 20 centrifugation (1000 rpm, 5 min at 4°C). The medium was aspirated and replaced with murine anti-HLA-DR antibody, diluted 1:3 in RPMI-1640 medium, and incubated for 30 min on ice. The cell suspension was mixed frequently.

- The cells were washed x2 with cold RPMI-1640 by centrifugation (1000 rpm, 5 min at 4°C) and then transferred to a sterile 15 mL centrifuge tube. The number of mononuclear
 25 cells were enumerated in an improved Neubauer counting chamber.

Sufficient magnetic beads (5 / mononuclear cell), coated with goat anti-mouse IgG, were removed from their stock bottle and placed into 5 mL of fresh medium (this washes away the toxic azide preservative). The medium was removed by immobilizing the beads on a magnet and is replaced with fresh medium.

- 30 The beads were mixed with the cells and the suspension was incubated for 30 min on ice. The suspension was mixed frequently. The bead-coated cells were immobilized on a magnet and the remaining cells (osteoclast-rich fraction) were decanted into a sterile 50 mL centrifuge tube. Fresh medium was added to the bead-coated cells to dislodge any

trapped osteoclasts. This wash process was repeated x10. The bead-coated cells were discarded.

The osteoclasts were enumerated in a counting chamber, using a large-bore disposable plastic pasteur pipette to charge the chamber with the sample. The cells were pelleted by centrifugation and the density of osteoclasts adjusted to $1.5 \times 10^4/\text{mL}$ in EMEM medium, supplemented with 10% fetal calf serum and 1.7g/litre of sodium bicarbonate. 3 mL aliquots of the cell suspension (per treatment) were decanted into 15 mL centrifuge tubes. These cells were pelleted by centrifugation. To each tube 3 mL of the appropriate treatment was added (diluted to 50 uM in the EMEM medium). Also included were appropriate vehicle controls, a positive control (87MEM1 diluted to 100 ug/mL) and an isotype control (IgG2a diluted to 100 ug/mL). The tubes were incubate at 37°C for 30 min.

0.5 mL aliquots of the cells were seeded onto sterile dentine slices in a 48-well plate and incubated at 37°C for 2 h. Each treatment was screened in quadruplicate. The slices were washed in six changes of warm PBS (10 mL / well in a 6-well plate) and then placed into fresh treatment or control and incubated at 37°C for 48 h. The slices were then washed in phosphate buffered saline and fixed in 2% glutaraldehyde (in 0.2M sodium cacodylate) for 5 min., following which they were washed in water and incubated in buffer for 5 min at 37°C. The slices were then washed in cold water and incubated in cold acetate buffer / fast red garnet for 5 min at 4°C. Excess buffer was aspirated, and the slices were air dried following a wash in water.

The TRAP positive osteoclasts were enumerated by bright-field microscopy and were then removed from the surface of the dentine by sonication. Pit volumes were determined using the Nikon/Lasertec ILM21W confocal microscope.

General

Nuclear magnetic resonance spectra were recorded at either 250 or 400 MHz using, respectively, a Bruker AM 250 or Bruker AC 400 spectrometer. CDCl_3 is deuteriochloroform, $\text{DMSO}-d_6$ is hexadeuteriodimethylsulfoxide, and CD_3OD is tetradeuteriomethanol. Chemical shifts are reported in parts per million (d) downfield from the internal standard tetramethylsilane. Abbreviations for NMR data are as follows: s = singlet, d = doublet, t = triplet, q = quartet, m = multiplet, dd = doublet of doublets, dt = doublet of triplets, app = apparent, br = broad. J indicates the NMR coupling constant measured in Hertz. Continuous wave infrared (IR) spectra were recorded on a Perkin-Elmer 683 infrared spectrometer, and Fourier transform infrared (FTIR) spectra were

recorded on a Nicolet Impact 400 D infrared spectrometer. IR and FTIR spectra were recorded in transmission mode, and band positions are reported in inverse wavenumbers (cm^{-1}). Mass spectra were taken on either VG 70 FE, PE Syx API III, or VG ZAB HF instruments, using fast atom bombardment (FAB) or electrospray (ES) ionization techniques. Elemental analyses were obtained using a Perkin-Elmer 240C elemental analyzer. Melting points were taken on a Thomas-Hoover melting point apparatus and are uncorrected. All temperatures are reported in degrees Celsius.

Analtech Silica Gel GF and E. Merck Silica Gel 60 F-254 thin layer plates were used for thin layer chromatography. Both flash and gravity chromatography were carried out on E. Merck Kieselgel 60 (230-400 mesh) silica gel.

Where indicated, certain of the materials were purchased from the Aldrich Chemical Co., Milwaukee, Wisconsin, Chemical Dynamics Corp., South Plainfield, New Jersey, and Advanced Chemtech, Louisville, Kentucky.
